

Explanation A

The method `tanh(real, img)` calculates a complex number. The assertion in line 4 checks if the method outputs the same value as the expected complex number `Complex(1, 1)`. Internally, the method computes the values of the variables `real2` and `img2` based on the method's `real` and `img` parameters.

However,

- In V1, line 9, the method checks whether `real` is ≤ 20 , which evaluates to `false`.

Therefore, the code inside this "if" block is not executed. The next check, if `img` is ≥ 1 in line 20, evaluates to `true`.

The values of `real2` and `img2` are thus calculated by adding `img` to `real2` and `img2` respectively.

- In V2, due to the change in line 9, the method rather checks whether `real` is ≥ 20 , which evaluates to `true`. This leads to `real2` being calculated as half the value of the exponential of `real` and `img2` being calculated as a function of `img`.

In summary, the change in line 9 leads to a different block of code being executed in V1 and V2. In V1, `real2` and `img2` are

directly incremented by the value of `img`.

In V2, `real2` and `img2` are calculated through more complex mathematical operations. The calculations in V2 cause the resulting complex number to differ from the expected `Complex(1, 1)` value in the assertion in line 4.

Explanation B

The method `tanh(real, img)` calculates a complex number. The assertion in line 4 checks if the method outputs the same value as the expected complex number `Complex(1, 1)`. Internally, the method computes the values of the variables `real2` and `img2` based on the method's `real` and `img` parameters.

However,

- In V1, line 9, the method checks whether `real` is ≤ 20 , which evaluates to `false`.

Therefore, the code inside this "if" block is not executed. The next check, if `img` is ≥ 1 in line 20, evaluates to `true`.

The values of `real2` and `img2` are thus calculated by adding `img` to `real2` and `img2` respectively.

- In V2, due to the change in line 9, the method rather checks whether `real` is ≥ 20 , which evaluates to `true`. This leads to `real2` being calculated as half the value of the exponential of `real`.

In lines 11-18, the value of `k` is calculated as a multiplication of `img` and 0.6366197725814; the value of `a` – as a multiplication of `-k` and 1.570796251296997; the values of `remA` – as a manipulation over the values of `img`, `a`, and `k`; the value of `remB` – as a manipulation `remA`. Ultimately, `img2` is assigned the value of `remB*5` in line 18.

In summary, the change in line 9 leads to a different block of code being executed in V1 and V2. In V1, `real2` and `img2` are

directly incremented by the value of `img`.

In V2, `real2` and `img2` are calculated through more complex mathematical operations. The calculations in V2 cause the resulting complex number to differ from the expected `Complex(1, 1)` value in the assertion in line 4.

Explanation C

The method `tanh(real, img)` calculates a complex number. The assertion in line 4 checks if the method outputs the same value as the expected complex number `Complex(1, 1)`. Internally, the method computes the value of the variables `real2` and `img2` based on its `real` and `img` parameters,

which are initialized to `positive infinity` and 1, in lines 2 and 3, respectively.

The values of `real2` and `img2` are first initialized to 0 in lines 7 and 8, respectively.

However,

- In V1, line 9, the method checks whether `real` is ≤ 20 , which evaluates to `false`

as `real` is `positive infinity`.

Therefore, the code inside this "if" block is not executed. The next check, if `img` is ≥ 1 in line 20, evaluates to `true` as `img` is 1.

The values of `real2` and `img2` are thus calculated by adding `img` to `real2` and `img2` respectively, resulting in the values of `real2` and `img2` being 1 each.

- In V2, due to the change in line 9, the method rather checks whether `real` is ≥ 20 , which evaluates to `true`. This leads to `real2` being calculated as half the value of the exponential of `real` and `img2` being calculated as a function of `img`.

In summary, the change in line 9 leads to a different block of code being executed in V1 and V2. In V1, `real2` and `img2` are

initialized as 0 and then

directly incremented by the value of `img`,

which is 1.

In V2, `real2` and `img2` are calculated through more complex mathematical operations. The calculations in V2 cause the resulting complex number to differ from the expected `Complex(1, 1)` value in the assertion in line 4.
